Why Sinusoidal Steady-State?
Compared with general transient case, sinusoidal case is very easy
\[ \frac{\partial}{\partial t} \rightarrow j\omega \]
Sinusoidal steady state has many important applications for RF/microwave circuits
At high frequency, T-lines are like interconnect for distances on the order of \( \lambda \)
Shorted or open T-lines are good resonators
T-lines are useful for impedance matching
Typical RF system modulates a sinusoidal carrier (either frequency or phase)

If the modulation bandwidth is much smaller than the carrier, the system looks like it’s excited by a pure sinusoid

Cell phones are a good example. The carrier frequency is about 1 GHz and the voice digital modulation is about 200 kHz (GSM) or 1.25 MHz (CDMA), less than a 0.1% of the bandwidth/carrier

Even a system like WiFi grabbing multiple channels might be 80 MHz wide, so over a 5 GHz carrier, it’s still a small fractional bandwidth
Generalized Distributed Circuit Model

- $Z'$: impedance per unit length (e.g. $Z' = j\omega L' + R'$)
- $Y'$: admittance per unit length (e.g. $Y' = j\omega C' + G'$)
- A lossy T-line might have the following form (but we’ll analyze the general case)
Applying KCL and KVL to a infinitesimal section

\[ v(z + \delta z) - v(z) = -Z' \delta zi(z) \]

\[ i(z + \delta z) - i(z) = -Y' \delta zv(z) \]

Taking the limit as before \((\delta z \to 0)\)

\[ \frac{dv}{dz} = -Zi(z) \]

\[ \frac{di}{dz} = -Yv(z) \]
Taking derivatives (notice $z$ is the only variable) we arrive at

\[
\frac{d^2v}{dz^2} = -Z \frac{di}{dz} = YZv(z) = \gamma^2 v(z)
\]

\[
\frac{d^2i}{dz^2} = -Y \frac{dv}{dz} = YZi(z) = \gamma^2 i(z)
\]

Where the propagation constant $\gamma$ is a complex function

\[
\gamma = \alpha + j\beta = \sqrt{(R' + j\omega L')(G' + j\omega C')}
\]

The general solution to $D^2 G - \gamma^2 G = 0$ is $e^{\pm\gamma z}$
Lossless Lines
\(v(z) = V^+ e^{-\gamma z} + V^- e^{\gamma z}\)

\(i(z) = \frac{V^+}{Z_0} e^{-\gamma z} - \frac{V^-}{Z_0} e^{\gamma z}\)

- The voltage and current are related (just as before, but now easier to derive). \(Z_0 = \sqrt{\frac{Z'}{Y'}}\) is the characteristic impedance of the line (function of frequency with loss).
- For a lossless line we discussed before, \(Z' = j\omega L'\) and \(Y' = j\omega C'\). Propagation constant is imaginary
  \[\gamma = \sqrt{j\omega L'j\omega C'} = j\sqrt{L'C'}\omega\]
- The characteristic impedance is real
  \[Z_0 = \sqrt{\frac{L'}{C'}}\]
- \(\beta\) is like the spatial frequency, also known as the wave number
- You might prefer to think of it in terms of wavelength \(\lambda\),
  \[\beta = \frac{2\pi}{\lambda}\]
Recall that the real voltages and currents are the $\mathbb{R}$ and $\mathbb{I}$ parts of

$$v(z, t) = e^{\pm \gamma z} e^{j \omega t} = e^{j \omega t \pm \beta z}$$

Thus the voltage/current waveforms are sinusoidal in space and time.

Sinusoidal source voltage is transmitted unaltered onto T-line (with delay).

If there is loss, then $\gamma$ has a real part $\alpha$, and the wave decays or grows on the T-line

$$e^{\pm \gamma z} = e^{\pm \alpha z} e^{\pm j \beta z}$$

The first term represents amplitude response of the T-line.
For a passive line, we expect the amplitude to decay due to loss on the line.

The speed of the wave is derived as before. In order to follow a constant point on the wavefront, you have to move with velocity

\[
\frac{d}{dt} (\omega t \pm \beta z = \text{constant})
\]

Or, \( v = \frac{dz}{dt} = \pm \frac{\omega}{\beta} = \pm \sqrt{\frac{1}{L'C'}} \)
Okay, lossless line means $\gamma = j\beta$ ($\alpha = 0$), and $\Im(Z_0) = 0$ (real characteristic impedance independent of frequency)

The voltage/current phasors take the standard form

$$v(z) = V^+ e^{-\gamma z} + V^- e^{\gamma z}$$

$$i(z) = \frac{V^+}{Z_0} e^{-\gamma z} - \frac{V^-}{Z_0} e^{\gamma z}$$
Lossless T-Line Termination (cont)

At load \( Z_L = \frac{v(0)}{i(0)} = \frac{V^+ + V^-}{V^+ - V^-} Z_0 \)

The reflection coefficient has the same form

\[
\rho_L = \frac{Z_L - Z_0}{Z_L + Z_0}
\]

Can therefore write

\[
v(z) = V^+ \left( e^{-j\beta z} + \rho_L e^{j\beta z} \right)
\]

\[
i(z) = \frac{V^+}{Z_0} \left( e^{-j\beta z} - \rho_L e^{j\beta z} \right)
\]
Standing Waves and VSWR
Let’s calculate the average power dissipation on the line at point $z$

$$P_{av}(z) = \frac{1}{2} \Re [v(z)i(z)^*]$$

Or using the general solution

$$P_{av}(z) = \frac{1}{2} \frac{|V^+|^2}{Z_0} \Re \left( (e^{-j\beta z} + \rho_L e^{j\beta z}) (e^{j\beta z} - \rho_L^* e^{-j\beta z}) \right)$$

The product in the $\Re$ terms can be expanded into four terms

$$1 + \rho_L e^{2j\beta z} - \rho_L^* e^{-2j\beta z} - |\rho_L|^2$$

Notice that $a - a^* = 2j\Im(a)$
The average power dissipated at $z$ is therefore

$$P_{av} = \frac{|V|^2}{2Z_0} \left(1 - |\rho_L|^2\right)$$

- Power flow is constant (independent of $z$) along line (lossless)
- No power flows if $|\rho_L| = 1$ (open or short)
- Even though power is constant, voltage and current are not!
When the termination is matched to the line impedance \( Z_L = Z_0 \), \( \rho_L = 0 \) and thus the voltage along the line \( |v(z)| = |V^+| \) is constant. Otherwise

\[
|v(z)| = |V^+||1 + \rho_L e^{2j\beta z}| = |V^+||1 + \rho_L e^{-2j\beta \ell}|
\]

The voltage magnitude along the line can be written as

\[
|v(-\ell)| = |V^+||1 + |\rho_L| e^{j(\theta - 2\beta \ell)}|
\]

The voltage is maximum when the \( 2\beta \ell \) is equal to \( \theta + 2k\pi \), for any integer \( k \); in other words, the reflection coefficient phase modulo \( 2\pi \)

\[
V_{max} = |V^+|(1 + |\rho_L|)
\]
Similarly, minimum when $\theta + k\pi$, where $k$ is an integer $k \neq 0$

$$V_{min} = |V^+|(1 - |\rho_L|)$$

The ratio of the maximum voltage to minimum voltage is an important metric and commonly known as the voltage standing wave ratio, VSWR (sometimes pronounced viswar), or simply the standing wave ratio SWR

$$V_{SWR} = \frac{V_{max}}{V_{min}} = \frac{1 + |\rho_L|}{1 - |\rho_L|}$$

It follows that for a shorted or open transmission line the VSWR is infinite, since $|\rho_L| = 1$. 

Physically the maxima occur when the reflected wave adds in phase with the incoming wave, and minima occur when destructive interference takes place. The distance between maxima and minima is $\pi$ in phase, or $2\beta \delta x = \pi$, or

$$\delta x = \frac{\pi}{2\beta} = \frac{\lambda}{4}$$

VSWR is important because it can be deduced with a relative measurement. Absolute measurements are difficult at microwave frequencies. By measuring VSWR, we can readily calculate $|\rho_L|$. 
By measuring the location of the voltage minima from an unknown load, we can solve for the load reflection coefficient phase $\theta$

$$\psi_{\text{min}} = \theta - 2\beta \ell_{\text{min}} = \pm \pi$$

Note that

$$|v(-\ell_{\text{min}})| = |V^+||1 + |\rho_L|e^{j\psi_{\text{min}}}|$$

Thus an unknown impedance can be characterized at microwave frequencies by measuring VSWR and $\ell_{\text{min}}$ and computing the load reflection coefficient. This was an important measurement technique that has been largely supplanted by a modern network analyzer with built-in digital calibration and correction.
Consider a transmission line terminated in a load impedance $Z_L = 2Z_0$. The reflection coefficient at the load is purely real:

$$\rho_L = \frac{z_L - 1}{z_L + 1} = \frac{2 - 1}{2 + 1} = \frac{1}{3}$$

Since $1 + |\rho_L| = 4/3$ and $1 - |\rho_L| = 2/3$, the VSWR is equal to 2.

Since the load is real, the voltage minima will occur at a distance of $\lambda/4$ from the load.
Impedance of T-Lines ("Ohm’s Law inFreq Domain")
Impedance of T-Line (I)

- We have seen that the voltage and current along a transmission line are altered by the presence of a load termination. At an arbitrary point \( z \), wish to calculate the input impedance, or the ratio of the voltage to current relative to the load impedance \( Z_L \)

\[
Z_{in}(-\ell) = \frac{v(-\ell)}{i(-\ell)}
\]

- It shall be convenient to define an analogous reflection coefficient at an arbitrary position along the line

\[
\rho(-\ell) = \frac{V^- e^{-j\beta\ell}}{V^+ e^{j\beta\ell}} = \rho_L e^{-2j\beta\ell}
\]
\( \rho(z) \) has a constant magnitude but a periodic phase. From this we may infer that the input impedance of a transmission line is also periodic (relation between \( \rho \) and \( Z \) is one-to-one)

\[
Z_{in}(-\ell) = Z_0 \frac{1 + \rho_L e^{-2j\beta \ell}}{1 - \rho_L e^{-2j\beta \ell}}
\]

The above equation is of paramount important as it expresses the input impedance of a transmission line as a function of position \( \ell \) away from the termination.
This equation can be transformed into another more useful form by substituting the value of $\rho_L$

$$\rho_L = \frac{Z_L - Z_0}{Z_L + Z_0}$$

$$Z_{in}(-\ell) = Z_0 \frac{Z_L(1 + e^{-2j\beta\ell}) + Z_0(1 - e^{-2j\beta\ell})}{Z_0(1 + e^{-2j\beta\ell}) + Z_L(1 - e^{-2j\beta\ell})}$$

Using the common complex expansions for sine and cosine, we have

$$\tan(x) = \frac{\sin(x)}{\cos(x)} = \frac{(e^{ix} - e^{-ix})/2j}{(e^{ix} + e^{-ix})/2}$$
The expression for the input impedance is now written in the following form

\[ Z_{in}(-\ell) = Z_0 \frac{Z_L + jZ_0 \tan(\beta \ell)}{Z_0 + jZ_L \tan(\beta \ell)} \]

This is the most important equation of the lecture, known sometimes as the “transmission line equation”
The shorted transmission line has infinite VSWR and \( \rho_L = -1 \). Thus the minimum voltage \( V_{\text{min}} = |V^+|(1 - |\rho_L|) = 0 \), as expected. At any given point along the transmission line

\[
\nu(z) = V^+ (e^{-j\beta z} - e^{j\beta z}) = -2jV^+ \sin(\beta z)
\]

whereas the current is given by

\[
i(z) = \frac{V^+}{Z_0} (e^{-j\beta z} + e^{j\beta z})
\]

or

\[
i(z) = \frac{2V^+}{Z_0} \cos(\beta z)
\]
The impedance at any point along the line takes on a simple form

\[ Z_{in}(-\ell) = \frac{v(-\ell)}{i(-\ell)} = jZ_0 \tan(\beta\ell) \]

This is a special case of the more general transmission line equation with \( Z_L = 0 \).

Note that the impedance is purely imaginary since a shorted lossless transmission line cannot dissipate any power.

We have learned, though, that the line stores reactive energy in a distributed fashion.
A plot of the input impedance as a function of $z$ is shown below.

The tangent function takes on infinite values when $\beta \ell$ approaches $\pi/2$ modulo $2\pi$. 
Shorted transmission line can have infinite input impedance!

This is particularly surprising since the load is in effect transformed from a short of $Z_L = 0$ to an infinite impedance.

A plot of the voltage/current as a function of $z$ is shown below.

\[ v(z) = Z_0 \frac{v}{v^+} \]
\[ i(z) = Z_0 \frac{i}{i(-\lambda/4)} \]

\[ v(\lambda/4) \]
\[ i(\lambda/4) \]
- $\ell \ll \lambda/4 \rightarrow$ inductor
- $\ell < \lambda/4 \rightarrow$ inductive reactance
- $\ell = \lambda/4 \rightarrow$ open (acts like resonant parallel LC circuit)
- $\ell > \lambda/4$ but $\ell < \lambda/2 \rightarrow$ capacitive reactance
- And the process repeats ...
The open transmission line has infinite VSWR and $\rho_L = 1$. At any given point along the transmission line

$$v(z) = V^+(e^{-j\beta z} + e^{j\beta z}) = 2V^+ \cos(\beta z)$$

whereas the current is given by

$$i(z) = \frac{V^+}{Z_0}(e^{-j\beta z} - e^{j\beta z})$$

or

$$i(z) = \frac{-2jV^+}{Z_0} \sin(\beta z)$$
The impedance at any point along the line takes on a simple form

\[ Z_{in}(-\ell) = \frac{v(-\ell)}{i(-\ell)} = -jZ_0 \cot(\beta \ell) \]

This is a special case of the more general transmission line equation with \( Z_L = \infty \).

Note that the impedance is purely imaginary since an open lossless transmission line cannot dissipate any power.

We have learned, though, that the line stores reactive energy in a distributed fashion.
A plot of the input impedance as a function of $z$ is shown below

The cotangent function takes on zero values when $\beta \ell$ approaches $\pi/2$ modulo $2\pi$
Open transmission line can have zero input impedance!

This is particularly surprising since the open load is in effect transformed from an open.

A plot of the voltage/current as a function of $z$ is shown below.
Open Line Reactance

- \( \ell \ll \lambda/4 \rightarrow \) capacitor
- \( \ell < \lambda/4 \rightarrow \) capacitive reactance
- \( \ell = \lambda/4 \rightarrow \) short (acts like resonant series LC circuit)
- \( \ell > \lambda/4 \) but \( \ell < \lambda/2 \) \( \rightarrow \) inductive reactance
- And the process repeats ...

\[
jX(z) = \begin{cases} jX(z) & \text{for } z < \frac{\lambda}{2} \\ 0 & \text{for } z = \frac{\lambda}{2} \\ jX(z) & \text{for } z > \frac{\lambda}{2} \end{cases}
\]

\( z = \frac{\lambda}{\lambda} \)
Plug into the general T-line equation for any multiple of $\lambda/2$

$$Z_{in}(-m\lambda/2) = Z_0 \frac{Z_L + jZ_0 \tan(-\beta \lambda/2)}{Z_0 + jZ_L \tan(-\beta \lambda/2)}$$

- $\beta \lambda m/2 = \frac{2\pi}{\lambda} \frac{\lambda m}{2} = \pi m$
- $\tan m\pi = 0$ if $m \in \mathbb{Z}$
- $Z_{in}(-\lambda m/2) = Z_0 \frac{Z_L}{Z_0} = Z_L$
- Impedance does not change ... it’s periodic about $\lambda/2$ (not $\lambda$)
Plug into the general T-line equation for any multiple of $\lambda/4$

- $\beta \lambda m/4 = \frac{2\pi}{\lambda} \frac{\lambda m}{4} = \frac{\pi}{2} m$
- $\tan m\frac{\pi}{2} = \infty$ if $m$ is an odd integer

- $Z_{in}(-\lambda m/4) = \frac{Z_0^2}{Z_L}$

$\lambda/4$ line transforms or “inverts” the impedance of the load
